

INVESTOR IN PEOPLE

The Patent Office
Concept House
Cardiff Road
Newport
South Wales
NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

I also certify that by virtue of an assignment registered under the Patents Act 1977, the application is now proceeding in the name as substituted.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

5 METHOD FOR PROVIDING DENSE PARTICLE COMPOSITIONS
 FOR USE IN TRANSDERMAL PARTICLE DELIVERY

Technical Field

10 The invention relates to a method for
 densifying processed pharmaceutical compositions. More
 particularly, the invention relates to a method for
 forming dense, substantially solid particles from non-
 dense particulate pharmaceutical compositions such as
15 ~~those prepared using freeze-drying or spray drying~~
 techniques. The densified compositions obtained using
 the method are particularly suitable for transdermal
 particle delivery from a needleless syringe system.

Background of the Invention

20 The ability to deliver drugs through skin
 surfaces (transdermal delivery) provides many advantages
 over oral or parenteral delivery techniques. In
 particular, transdermal delivery provides a safe,
 convenient and noninvasive alternative to traditional
25 drug administration systems, conveniently avoiding the
 major problems associated with oral delivery, e.g.,
 variable rates of absorption and metabolism,
 gastrointestinal irritation and/or bitter or unpleasant
 drug tastes. Transdermal delivery also avoids problems
30 associated with parenteral delivery, e.g., needle pain,
 the risk of introducing infection to treated individuals,
 the risk of contamination or infection of health care
 workers caused by accidental needle-sticks and the
 disposal of used needles. In addition, such delivery

affords a high degree of control over blood concentrations of administered drugs.

However, despite its clear advantages, transdermal drug delivery presents a number of its own inherent logistical problems. The passive delivery of drugs through intact skin necessarily entails the transport of molecules through a number of structurally different tissues, including the stratum corneum, the viable epidermis, the papillary dermis, and the capillary walls in order for the drug to gain entry into the blood or lymph system. Transdermal delivery systems must therefore be able to overcome the various resistances presented by each type of tissue. In light of the above, a number of alternatives to passive transdermal delivery have been developed. These alternatives include the use of skin penetration enhancing agents, or "permeation enhancers," to increase skin permeability, as well as non-chemical modes such as the use of iontophoresis, electroporation or ultrasound. However, such techniques often give rise to unwanted side effects, such as skin irritation or sensitization. Thus, the number of drugs that can be safely and effectively administered using traditional transdermal delivery methods has remained limited.

More recently, a novel transdermal drug delivery system that entails the use of a needleless syringe to fire solid drug-containing particles in controlled doses into and through intact skin has been described. In particular, commonly assigned U.S. Patent Application Serial Number 08/474,367, entitled "Transdermal Drug Delivery" and filed June 7, 1995 by Bellhouse et al. describes a needleless syringe that delivers pharmaceutical particles entrained in a supersonic gas flow. The needleless syringe is used for transdermal delivery of powdered drug compounds and

compositions, for delivery of genetic material into living cells (e.g., gene therapy) and for the delivery of biopharmaceuticals to skin, muscle, blood or lymph. The needleless syringe can also be used in conjunction with surgery to deliver drugs and biologics to organ surfaces, solid tumors and/or to surgical cavities (e.g., tumor beds or cavities after tumor resection). In theory, practically any pharmaceutical agent that can be prepared in a substantially solid, particulate form can be safely and easily delivered using such devices.

One particular needleless syringe generally comprises an elongate tubular nozzle having a rupturable membrane initially closing the passage through the nozzle and arranged substantially adjacent to the upstream end of the nozzle. Particles of a therapeutic agent to be delivered are disposed adjacent to the rupturable membrane and are delivered using an energizing means which applies a gaseous pressure to the upstream side of the membrane sufficient to burst the membrane and produce a supersonic gas flow (containing the pharmaceutical particles) through the nozzle for delivery from the downstream end thereof. The particles can thus be delivered from the needleless syringe at delivery velocities of between Mach 1 and Mach 8 which are readily obtainable upon the bursting of the rupturable membrane.

Another needleless syringe configuration generally includes the same elements as described above, except that instead of having the pharmaceutical particles entrained within a supersonic gas flow, the downstream end of the nozzle is provided with a bistable diaphragm which is moveable between a resting "inverted" position (in which the diaphragm presents a concavity on the downstream face to contain the pharmaceutical particles) and an active "everted" position (in which the diaphragm is outwardly convex on the downstream face as a

result of a supersonic shockwave having been applied to the upstream face of the diaphragm). In this manner, the pharmaceutical particles contained within the concavity of the diaphragm are expelled at a supersonic initial velocity from the device for transdermal delivery thereof to a targeted skin or mucosal surface.

Transdermal delivery using the above-described needleless syringe configurations is carried out with particles having an approximate size that generally ranges between 0.1 and 250 μm . For drug delivery, an optimal particle size is usually at least about 10 to 15 μm (the size of a typical cell). For gene delivery, an optimal particle size is generally substantially smaller than 10 μm . Particles larger than about 250 μm can also be delivered from the device, with the upper limitation being the point at which the size of the particles would cause untoward damage to the skin cells. The actual distance which the delivered particles will penetrate depends upon particle size (e.g., the nominal particle diameter assuming a roughly spherical particle geometry), particle density, the initial velocity at which the particle impacts the skin surface, and the density and kinematic viscosity of the skin. In this regard, optimal particle densities for use in needleless injection generally range between about 0.1 and 25 g/cm^3 , preferably between about 0.9 and 1.5 g/cm^3 , and injection velocities generally range between about 200 and 3,000 m/sec .

A particularly unique feature of the needleless syringe is the ability to closely control the depth of penetration of delivered particles, thereby allowing for targeted administration of pharmaceuticals to various sites. For example, particle characteristics and/or device operating parameters can be selected to provide penetration depths of less than about 1 mm for intra-

dermal delivery, or approximately 1-2 mm for sub-cutaneous delivery. One approach entails the selection of particle size, particle density and initial velocity to provide a momentum density (e.g., particle momentum
5 divided by particle frontal area) of between about 2 and 10 kg/sec/m, and more preferably between about 4 and 7 kg/sec/m. Such control over momentum density allows for precisely controlled, tissue-selective delivery of the pharmaceutical particles.

10 Accordingly, there is a need to provide a reliable method for preparing sufficiently dense particles (having a density of about 0.9 to 1.5 g/cm³) which have an average size of about 0.1 to 150 μ m from a wide variety of pharmaceutical compositions. The
15 densified pharmaceutical particles can thus be transdermally delivered to a subject using a needleless syringe system.

Summary of the Invention

20 In one embodiment of the invention, a method is provided for converting non-dense pharmaceutical powders or particulate formulations (e.g., having particle densities below that required for transdermal delivery at supersonic velocities) into densified particles that are
25 optimally suited for transdermal delivery using a needleless syringe. Such particles have an optimal particle density ranging from about 0.1 to about 25 g/cm³, preferably ranging from about 0.8 to about 3.0 g/cm³, and most preferably ranging from about 0.9 to
30 about 1.5 g/cm³. The densified particles are processed to obtain optimal particle sizes ranging from about 0.1 to about 250 μ m, preferably ranging from about 0.1 to about 150 μ m, and most preferably ranging from about 20 to about 60 μ m. The method entails the compaction of a
35 pharmaceutical composition using high pressure and,

optionally vacuum, to densify the composition. The resulting compacted material is then size-reduced using conventional methods to provide densified particles of optimized size.

5 In a related embodiment of the invention, a method is provided for optimizing the density and particle size of a particulate pharmaceutical composition that has particle size and density characteristics that fall within the above ranges using the above-described
10 compaction and size-reduction techniques. In this manner, the penetration depths that are obtained when the optimized particles are delivered at supersonic velocities using a needleless syringe can be adjusted to provide targeted intra-dermal delivery (e.g., the
15 particle size and density are optimized for penetration of less than about 1 mm) or sub-cutaneous delivery (e.g., the particle size and density are optimized for penetration of approximately 1-2 mm).

 In a further related embodiment, the invention
20 pertains to a method for optimizing the particle size and density of a lyophilized or spray-dried biopharmaceutical composition. The method entails the compaction of a lyophilized or spray-dried pharmaceutical powder to obtain a densified material. The densified material can
25 then be reground to produce compositions in which the individual particles approach the theoretical maximum density and are thus optimal for delivery by impact with and penetration into skin at supersonic velocities when delivered from a needleless syringe. In a particular
30 embodiment, lyophilized recombinant human growth hormone (rhGH) powder is densified to obtain particles in the range of about 20 to 50 μm and having a density of about 0.9 to 1.5 g/cc^3 . The densified rhGH particles are ideally suited for delivery from a needleless syringe
35 device.

These and other embodiments of the invention will readily occur to those of ordinary skill in the art in view of the disclosure herein.

5 Brief Description of the Drawings

Figure 1 depicts a comparison of the mean in vivo serum levels of recombinant human growth hormone (rhGH) in animals that were administered lyophilized rhGH powder by needleless injection (▲), densified rhGH particles (prepared by the method of the invention) by
10 needleless injection (■), or lyophilized rhGH powder by sub-cutaneous injection (●).

15 Detailed Description of the Preferred Embodiments

Before describing the present invention in detail, it is to be understood that this invention is not limited to particular pharmaceutical formulations or process parameters as such may, of course, vary. It is also to be understood that the terminology used herein is
20 for the purpose of describing particular embodiments of the invention only, and is not intended to be limiting.

All publications, patents and patent applications cited herein, whether *supra* or *infra*, are hereby incorporated by reference in their entirety.

25 It must be noted that, as used in this specification and the appended claims, the singular forms "a", "an" and "the" include plural referents unless the content clearly dictates otherwise. Thus, for example, reference to "a pharmaceutical agent" includes a mixture
30 of two or more pharmaceutical agents, reference to "an excipient" includes mixtures of two or more excipients, and the like.

A. Definitions

Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which the invention pertains. Although a number of methods and materials similar or equivalent to those described herein can be used in the practice of the present invention, the preferred materials and methods are described herein.

In describing the present invention, the following terms will be employed, and are intended to be defined as indicated below.

By "transdermal" delivery, applicants intend to include both transdermal (or "percutaneous") and transmucosal administration, i.e., delivery by passage of a drug or pharmaceutical agent through the skin or mucosal tissue. See, e.g., *Transdermal Drug Delivery: Developmental Issues and Research Initiatives*, Hadgraft and Guy (eds.), Marcel Dekker, Inc., (1989); *Controlled Drug Delivery: Fundamentals and Applications*, Robinson and Lee (eds.), Marcel Dekker Inc., (1987); and *Transdermal Delivery of Drugs*, Vols. 1-3, Kydonieus and Berner (eds.), CRC Press, (1987). Aspects of the invention which are described herein in the context of "transdermal" delivery, unless otherwise specified, are meant to apply to both transdermal and transmucosal delivery. That is, the compositions, systems, and methods of the invention, unless explicitly stated otherwise, should be presumed to be equally applicable with transdermal and transmucosal modes of delivery.

As used herein, the term "drug" or "pharmaceutical agent" intends any compound or composition of matter which, when administered to an organism (human or animal) induces a desired pharmacologic and/or physiologic effect by local and/or

systemic action. The term therefore encompasses those compounds or chemicals traditionally regarded as drugs, as well as biopharmaceuticals including molecules such as peptides, hormones, nucleic acids, gene constructs and the like. More particularly, the term "drug" or "pharmaceutical agent" includes compounds or compositions for use in all of the major therapeutic areas including, but not limited to, anti-infectives such as antibiotics and antiviral agents; analgesics and analgesic combinations; local and general anesthetics; anorexics; antiarthritics; antiasthmatic agents; anticonvulsants; antidepressants; antihistamines; anti-inflammatory agents; antinauseants; antineoplastics; antipruritics; antipsychotics; antipyretics; antispasmodics; cardiovascular preparations (including calcium channel blockers, beta-blockers, beta-agonists and antiarrhythmics); antihypertensives; diuretics; vasodilators; central nervous system stimulants; cough and cold preparations; decongestants; diagnostics; hormones; bone growth stimulants and bone resorption inhibitors; immunosuppressives; muscle relaxants; psychostimulants; sedatives; tranquilizers; proteins peptides and fragments thereof (whether naturally occurring, chemically synthesized or recombinantly produced); and nucleic acid molecules (polymeric forms of two or more nucleotides, either ribonucleotides (RNA) or deoxyribonucleotides (DNA) including both double- and single-stranded molecules, gene constructs, expression vectors, antisense molecules and the like).

The above drugs or pharmaceutical agents, alone or in combination with other drugs or agents, are typically prepared as pharmaceutical compositions which can contain one or more added materials such as carriers, vehicles, and/or excipients. "Carriers," "vehicles" and "excipients" generally refer to substantially inert

materials which are nontoxic and do not interact with other components of the composition in a deleterious manner. These materials can be used to increase the amount of solids in particulate pharmaceutical compositions, such as those prepared using spray-drying or lyophilization techniques. Examples of suitable carriers include water, silicone, gelatin, waxes, and like materials. Examples of normally employed "excipients," include pharmaceutical grades of dextrose, sucrose, lactose, trehalose, mannitol, sorbitol, inositol, dextran, starch, cellulose, sodium or calcium phosphates, calcium sulfate, citric acid, tartaric acid, glycine, high molecular weight polyethylene glycols (PEG), and combinations thereof.

"Gene delivery" refers to methods or systems for reliably inserting foreign DNA into host cells. Such methods can result in expression of non-integrated transferred DNA, extrachromosomal replication and expression of transferred replicons (e.g., episomes), or integration of transferred genetic material into the genomic DNA of host cells.

By "vector" is meant any genetic element, such as a plasmid, phage, transposon, cosmid, chromosome, virus, virion, etc., which is capable of replication when associated with the proper control elements and which can transfer gene sequences between cells.

B. General Methods

In one embodiment, the invention entails a procedure for forming dense particles from low density particulate pharmaceutical preparations. In particular, manufacturing processes for preparing pharmaceutical particles from delicate molecules such as proteins or peptides generally result in low density particles having either a hollow spherical or open lattice monolithic

structure. Such particles are poorly suited for use in
needleless syringe delivery systems, wherein the
particles must have sufficient physical strength to
withstand sudden acceleration to several times the speed
5 of sound and the impact with, and passage through, the
skin and tissue.

One common method of preparing pharmaceuticals,
particularly heat-sensitive biopharmaceutical particles,
is lyophilization (freeze-drying). Lyophilization
10 relates to a technique for removing moisture from a
material and involves rapid freezing at a very low
temperature, followed by rapid dehydration by sublimation
in a high vacuum. This technique typically yields low-
density porous particles having an open matrix structure.
15 Such particles are chemically stable, but are rapidly
reconstituted (disintegrated and/or brought into
solution) when introduced into an aqueous environment.
Exemplary biopharmaceuticals available as lyophilized
particles include recombinant human growth factor (e.g.,
20 Genotropin®, Pharmacia, Piscataway, NJ); somatrem (e.g.,
Protropin®, Genentech, S. San Francisco, CA); somatropin
(e.g., Humatrope®, Eli Lilly, Indianapolis, IN);
recombinant interferon α -2a (e.g., Roferon®-A, Hoffman-La
Roche, Nutley, NJ); recombinant interferon α -2b (e.g.,
25 Intron A®, Schering-Plough, Madison, NJ); and recombinant
alteplase (e.g., Activase®, Genentech, S. San Francisco,
CA).

Another method of preparing pharmaceutical
particles that is often used with delicate or heat-
30 sensitive biomolecules is spray-drying. Spray-drying
relates to the atomization of a solution of one or more
solids using a nozzle, spinning disk or other device,
followed by evaporation of the solvent from the droplets.
More particularly, spray-drying involves combining a
35 highly dispersed liquid pharmaceutical preparation (e.g.,

a solution, slurry, emulsion or the like) with a suitable volume of hot air to produce evaporation and drying of the liquid droplets. Spray-dried pharmaceuticals are generally characterized as homogenous spherical particles that are frequently hollow. Such particles have low density and exhibit a rapid rate of solution. Exemplary heat-sensitive pharmaceuticals that are prepared using spray-drying techniques include the amino acids, antibiotics such as aureomycin, bacitracin, penicillin and streptomycin; ascorbic acid; cascara extracts; pepsin and similar enzymes; protein hydrolysates; and thiamine.

When spray-dried and lyophilized pharmaceutical particles are ground or milled, they yield very small, light and non-dense particles that are poorly suited for delivery through skin or mucosal tissues. In particular, such particles, when delivered from a needleless syringe, are often too light to have the momentum necessary to penetrate intact skin (e.g., cross through the stratum corneum) and would thus fail to enter into systemic circulation. In this regard, the stratum corneum is a thin layer of dense packed, highly keratinized cells, generally about 10-15 μm thick and which covers most of the human body. The stratum corneum thus provides the primary skin barrier which a transdermally-delivered particle must cross.

Accordingly, the present method entails densifying such preparations to provide particles that are much better suited for delivery from a needleless syringe (e.g., substantially solid particles having a size of about 50 μm and a density of at least about 0.9 to 1.5 g/cc^3). In particular, the open lattice or hollow shell particles provided by spray-drying or lyophilization are condensed without heating or shear to provide dense materials that can be milled or otherwise size-reduced to yield pharmaceutical particles having

both size and density characteristics suitable for delivery by needleless injection.

Condensing of the spray-dried or lyophilized powders is conducted by compaction in a suitable press (e.g., a hydraulic press, tableting press or rotary press), wherein the powders are compressed at about 1,000 to 24,000 pounds/square inch (0.5 to 12 tons/square inch) for a suitable time. Compaction can be carried out under vacuum if desired. The resulting compacted material is then coarsely reground until visually broken up. The particle size is then reduced to about a 20 to 50 μm average size to yield a light pack density of around 0.9 to 1.5 g/cc^3 . Particle size reduction can be conducted using methods well known in the art including, but not limited to, roller milling, ball milling, hammer or impact milling, attrition milling, sieving, sonicating, or combinations thereof. The compression parameters and particle sizing will, of course, vary depending upon the starting material used, the desired target particle size and density, and like considerations. The starting material can be any pharmaceutical preparation having a particle size and density which one is desirous of changing to obtain more optimal size and density characteristics for use in needleless syringes. Particle density can be readily ascertained using known quantification techniques such as helium pycnometry and the like.

Thus, the method can be used to obtain particles having a size ranging from about 0.1 to about 250 μm , preferably about 0.1 to about 150 μm , and most preferably about 20 to about 60 μm ; and a particle density ranging from about 0.1 to about 25 g/cm^3 , preferably about 0.8 to about 3.0 g/cm^3 , and most preferably about 0.9 to about 1.5 g/cm^3 .

The above-described method can also be used to optimize the density and particle size of a particulate pharmaceutical composition that has particle size and density characteristics that fall within the above
5 ranges. In this manner, the penetration depths that are obtained when the optimized particles are delivered at supersonic velocities using a needleless syringe can be adjusted to provide targeted intra-dermal delivery (e.g., the particle size and density are optimized for
10 penetration of less than about 1 mm) or sub-cutaneous delivery (e.g., the particle size and density are optimized for penetration of approximately 1-2 mm).

However, as noted hereinabove, the invention is particularly suited for preparing densified particles
15 having optimized density from heat-sensitive biopharmaceutical preparations of peptides, polypeptides, proteins and other such biological molecules. Exemplary peptide and protein formulations which can be densified using the instant method include, without limitation,
20 insulin; calcitonin; octreotide; endorphin; liprecin; pituitary hormones (e.g., human growth hormone and recombinant human growth hormone (hGH and rhGH), HMG, desmopressin acetate, etc); follicle luteoids; growth factors (such as growth factor releasing factor (GFRF),
25 somatostatin, somatotropin and platelet-derived growth factor); asparaginase; chorionic gonadotropin; corticotropin (ACTH); erythropoietin (EPO); epoprostenol (platelet aggregation inhibitor); glucagon; interferons; interleukins; menotropins (urofollitropin follicle-
30 stimulating hormone (FSH) and luteinizing hormone (LH)); oxytocin; streptokinase; tissue plasminogen activator (TPA); urokinase; vasopressin; desmopressin; ACTH analogues; angiotensin II antagonists; antidiuretic hormone agonists; bradykinin antagonists; CD4 molecules;
35 antibody molecules and antibody fragments (e.g., Fab,

Fab₂, Fv and sFv molecules); IGF-1; neurotrophic factors; colony stimulating factors; parathyroid hormone and agonists; parathyroid hormone antagonists; prostaglandin antagonists; protein C; protein S; renin inhibitors; 5 thrombolytics; tumor necrosis factor (TNF); vaccines (particularly peptide vaccines including subunit and synthetic peptide preparations); vasopressin antagonists analogues; and α -1 antitrypsin. Additionally, non-dense preparations of vectors or gene constructs for use in 10 subsequent gene delivery are also particularly well suited for densification using the method of the present invention.

C. Experimental

15 Below are examples of specific embodiments for carrying out the present invention. The examples are offered for illustrative purposes only, and are not intended to limit the scope of the present invention in any way.

20 Efforts have been made to ensure accuracy with respect to numbers used (e.g., amounts, temperatures, etc.), but some experimental error and deviation should, of course, be allowed for.

25

Example 1

Densification of Recombinant

Human Growth Hormone (rhGH)

Lyophilized recombinant human growth hormone powder (Genotropin®, available from Pharmacia, 30 Piscataway, NJ) was obtained and reprocessed using the method of the invention. Particularly, approximately 30 mg of Genotropin was compacted under pressure using a Carver Laboratory Pellet Press (Model 3620, available from Carver, Inc., Wabash, IN). The pressure of 35 compaction was 15,000 lbs/in², which was applied for

approximately 45 seconds. A pellet was obtained which was ground using mortar and pestle until visually broken up. The resulting reduced pellet was then sieved using a 53 μ m sieve (Endecott, London). Particles having a size greater 53 μ m were selected and appropriate dosages thereof were measured into drug cassettes for delivery from a needleless syringe.

Example 2

Visual Assessment of rhGH Particle Penetration

Lyophilized recombinant human growth hormone (rhGH) powder, and densified rhGH particles prepared as described in Example 1 were administered to porcine subjects using a needleless syringe. The degree of particle penetration was visually ascertained as follows.

Genotropin® 36 IU lyophilized powder was milled gently, weighed into individual doses of approximately 0.8 mg powder and loaded into a needleless syringe device for delivery. Densified Genotropin® was prepared as described in Example 1 and approximately 0.8 mg of the densified particles were loaded into a needleless syringe device for delivery.

Porcine subjects were prepared by clipping a sufficient area on the hindquarters. The lyophilized powder and densified particles were delivered to the porcine skin under high velocity. Upon a side-by-side comparison, it was observed that a higher proportion of the densified particles penetrated the skin as evidenced by the visual presence of the lyophilized powder remaining largely on the surface of the skin while substantially no densified particles were observed to remain on the surface of the skin.

Example 3

Densification of Commonly Used Excipients

Finely ground powders of pharmaceutical grade mannitol and lactose were obtained and reprocessed using the method of the invention. Particularly, approximately 30 to 50 mg of mannitol or lactose were compacted under pressure using a Carver Laboratory Pellet Press (Model 3620, available from Carver, Inc., Wabash, IN). The pressure of compaction was 10,000 lbs/in² which was applied for approximately 30 seconds. The resulting compacted pellets were ground using mortar and pestle until visually broken up, and then sieved to select for particles having a size greater than about 50 μ m using the methods described in Example 1. In both the mannitol and the lactose preparations, a significant size reduction was observed when the compacted particles were compared against like weights of the non-densified starting materials.

Example 4

Serum Levels of Transdermally-Delivered rhGH

In order to determine the efficiency with which densified rhGH is delivered using a needleless syringe system, the following study was carried out. Three groups of 5 healthy New Zealand White rabbits were prepared by clipping the fur from the flank area to expose a sufficient area for delivery of lyophilized recombinant human growth hormone powder (rhGH) or densified rhGH by needleless syringe.

Approximately 0.8 mg of lyophilized Genotropin[®] powder was reconstituted into 1.8 mL of a suitable buffer without preservatives (e.g., sterile phosphate buffered saline (PBS)) to provide a Genotropin[®] solution having a concentration of 20 IU/mL. 1 mL dosages were withdrawn by syringe and gently mixed with 1 mL of buffer to

provide an injection solution having a concentration of 10 IU/mL.

Each animal in the first group were given 0.1 mL/kg of the injection solution by subcutaneous injection, and the injection site was observed to ensure that there was no leakage of the injected solution after administration. Venous blood samples were taken from the marginal ear vein of the right ear of each animal at 0, 30 minutes, 1, 2, 4, 6, 12 and 24 hours after administration. Serum levels of rhGH were ascertained using an immunoassay with labeled anti-rhGH antibodies. The mean serum levels of subcutaneously delivered Genotropin® (●) found in the animals of Group 1 at each time point are depicted in Figure 1.

Approximately 2 mg of lyophilized Genotropin® powder was loaded into a needleless syringe. The lyophilized powder was administered to each animal in the second group by needleless injection at high velocity. Venous blood samples were taken from the marginal ear vein of the right ear of each animal at 0, 30 minutes, 1, 2, 4, 6, 12 and 24 hours after administration. Serum levels of the administered rhGH were ascertained using an immunoassay with labeled anti-hGH antibodies. The mean serum levels of transdermally injected lyophilized Genotropin® powder (▲) found in the animals of Group 2 at each time point are depicted in Figure 1.

Approximately 2 mg of densified Genotropin® particles prepared as in Example 1 was loaded into a needleless syringe. The densified particles were administered to each animal in the third group by needleless injection at high velocity. Venous blood samples were taken from the marginal ear vein of the right ear of each animal at 0, 30 minutes, 1, 2, 4, 6, 12 and 24 hours after administration. Serum levels of the

administered rhGH were ascertained using an immunoassay with labeled anti-rhGH antibodies. The mean serum levels of transdermally injected densified Genotropin® particles (■) found in the animals of Group 3 at each time point are depicted in Figure 1.

As can be seen, markedly increased blood serum levels of the densified Genotropin® particles administered by needleless syringe were obtained as compared to the lyophilized Genotropin® powder.

Example 5

Determination of Optimum Conditions for Needleless Syringe Delivery of rhGH

In order to determine optimum conditions for delivery of rhGH using a needleless syringe delivery system, the following study is carried out. One group of 8 healthy New Zealand White rabbits (2 ± 0.25 kg) are prepared by clipping the fur from the flank area to expose a sufficient area for delivery of Lyophilized recombinant human growth hormone powder (rhGH) or densified rhGH by needleless syringe, sub-cutaneous (SC) or intravenous (IV) injection. The animals are weighed at the start of the study and on a weekly basis throughout the study to determine appropriate Genotropin® dosages. The animals remain in one large group to obtain statistically-significant data.

For an initial needleless syringe injection series, Genotropin® 36 IU lyophilized powder is milled gently and filled into a glass vial. The milled lyophilized powder is weighed into individual dosages and loaded into needleless syringe devices at approximately 0.8 mg powder/kg. The injection is conducted in the first week of the study, and multiple venous blood samples (1 mL whole blood) are taken from the marginal ear vein at times 0, 30 minutes, 1, 2, 4, 6, 12, 24 and

48 hours after administration. The animals are individually-housed at all times with food and water available ad libitum.

5 Blood samples are handled and processed as follows: each venous blood sample is allowed to clot at ambient temperature for approximately 30 minutes and then left for an additional 30 minutes at approximately 4 °C. Clotted samples are centrifuged for 10 minutes and the serum is aspirated and stored at -20 °C for analysis.

10 In the second week of the study, (approximately 1 week following the initial needleless injection), the animals are administered a Genotropin® formulation prepared as follows: 36 IU (approximately 30 mg) of the lyophilized Genotropin® powder is reconstituted into 1.8
15 mL of a suitable buffer without preservatives (e.g., sterile phosphate buffered saline (PBS)) to provide a Genotropin® solution having a concentration of 20 IU/mL. 1 mL dosages are withdrawn by syringe and gently mixed with 1 mL of buffer to provide an injection solution
20 having a concentration of 10 IU/mL. Each animal is given an IV injection of 0.1 mL/kg of the solution in the left ear.

Following IV injection, multiple venous blood samples are taken from the marginal ear vein of the right
25 ear at times 0, 5, 10, 30 minutes, 1, 2, 4, 6 and 12 hours after injection.

In the third week of the study, the animals are administered 0.1 mL/kg of a buffered Genotropin® solution (prepared as above) by sub-cutaneous injection. The
30 injection site is observed to ensure that there is no leakage after administration. Following the SC injections, multiple venous blood samples are taken from the marginal ear vein of the right ear at times 0, 30 minutes, 1, 2, 4, 6, 12, 24 and 48 hours after
35 administration.

In the fourth week of the study, approximately 0.8 mg powder/kg of densified Genotropin® particles (prepared as described in Example 1) are administered to each animal using a needleless syringe, and multiple
5 venous blood samples are taken from the marginal ear vein of the right ear at times 0, 30 minutes, 1, 2, 4, 6, 12, 24 and 48 hours after administration.

Serum rhGH levels are determined as previously described and pharmacokinetic variables are calculated
10 for each drug administration technique. It is expected that needleless syringe administration of the densified Genotropin® particles will result in achieving and maintaining in vivo therapeutic levels of the administered drug.

Example 6

Bio-Activity of Densified rhGH Delivered In Vivo to Growth Hormone-Deficient Rats

To evaluate the bio-activity of recombinant
20 human growth hormone that has been densified using the method of the present invention the following study is carried out.

Dwarf or hypophysectomized (growth hormone-deficient) rats are administered pharmaceutical
25 preparations containing either: densified Genotropin® particles; lyophilized Genotropin® powder; or placebo at approximately 4 IU rhGH per animal/week by daily subcutaneous (SC) injection. In particular, on 5 successive days, fur from the peritoneal region of the animal
30 subjects is clipped prior to administration of the densified rhGH, the lyophilized rhGH or the placebo by SC injection. Body weight and, if desired, bone size and length are monitored on a daily basis.

Bio-activity of the densified rhGH particle
35 formulation is determined by measuring body weight change

over time. It is expected that the densified rhGH particle formulation will retain sufficient bio-activity.
